

# Three Dimensions of Sentence Prosody and their (Non-)Interactions

Michael Wagner & Michael McAuliffe. McGill University

PaPE

June 12-14 2017

## Three dimensions of Prosody:

Constituent structure ~ Phrasing

[AB]C vs. A[BC]

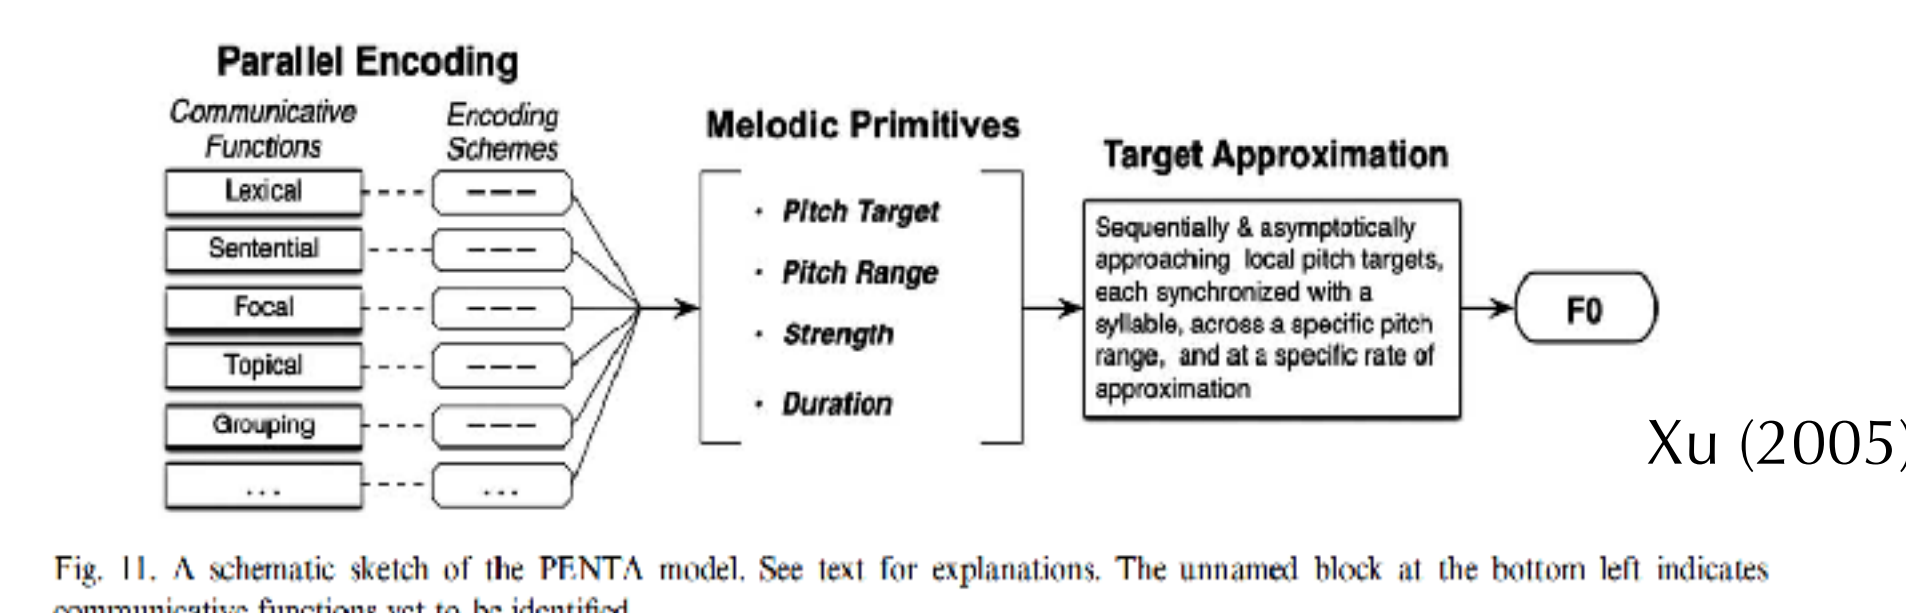

Focus ~ Prominence

ABC vs. ABC

Speech Act ~ Tune

ABC! vs. ABC?

## (How) Do the three dimensions interact?

## Test Case: F0 Scaling for Phrasing

- ★ Are there scaling effects in postfocally?
- ★ Are scaling effects different in questions?

- ★ Questions with initial focus consist of single Intonational Phrase (e.g., Pierrehumbert 1980)
- ★ Prominence should neutralize postfocal phrasing
- ★ "[...] at least one pitch accent somewhere in every (prosodic) phrase [...]" (Beckman 1996)
- ★ CF: Norcliffe & Jaeger 2005
- ★ Separate F0 function of Tune, Prominence, Phrasing
- ★ They could affect F0 without interacting
- ★ Direct phonetic correlates of semantic/syntactic functions (but see Ladd 2008 why phonological mediation is needed)
- ★ Only crucial here: independent representation of dimensions

Current AM Models: Yes

Overlay Models: No

Do prominence and tune interact with scaling?

## Production Experiment

[AB]C

ABC I thought they said Sarah or Marvin, and Nolan arrived.  
 ABC I thought they said Marion or Sarah, and Nolan arrived.  
 ABC I thought they said Marion or Marvin, and Sarah arrived.  
 ABC I thought they said Sarah arrived.

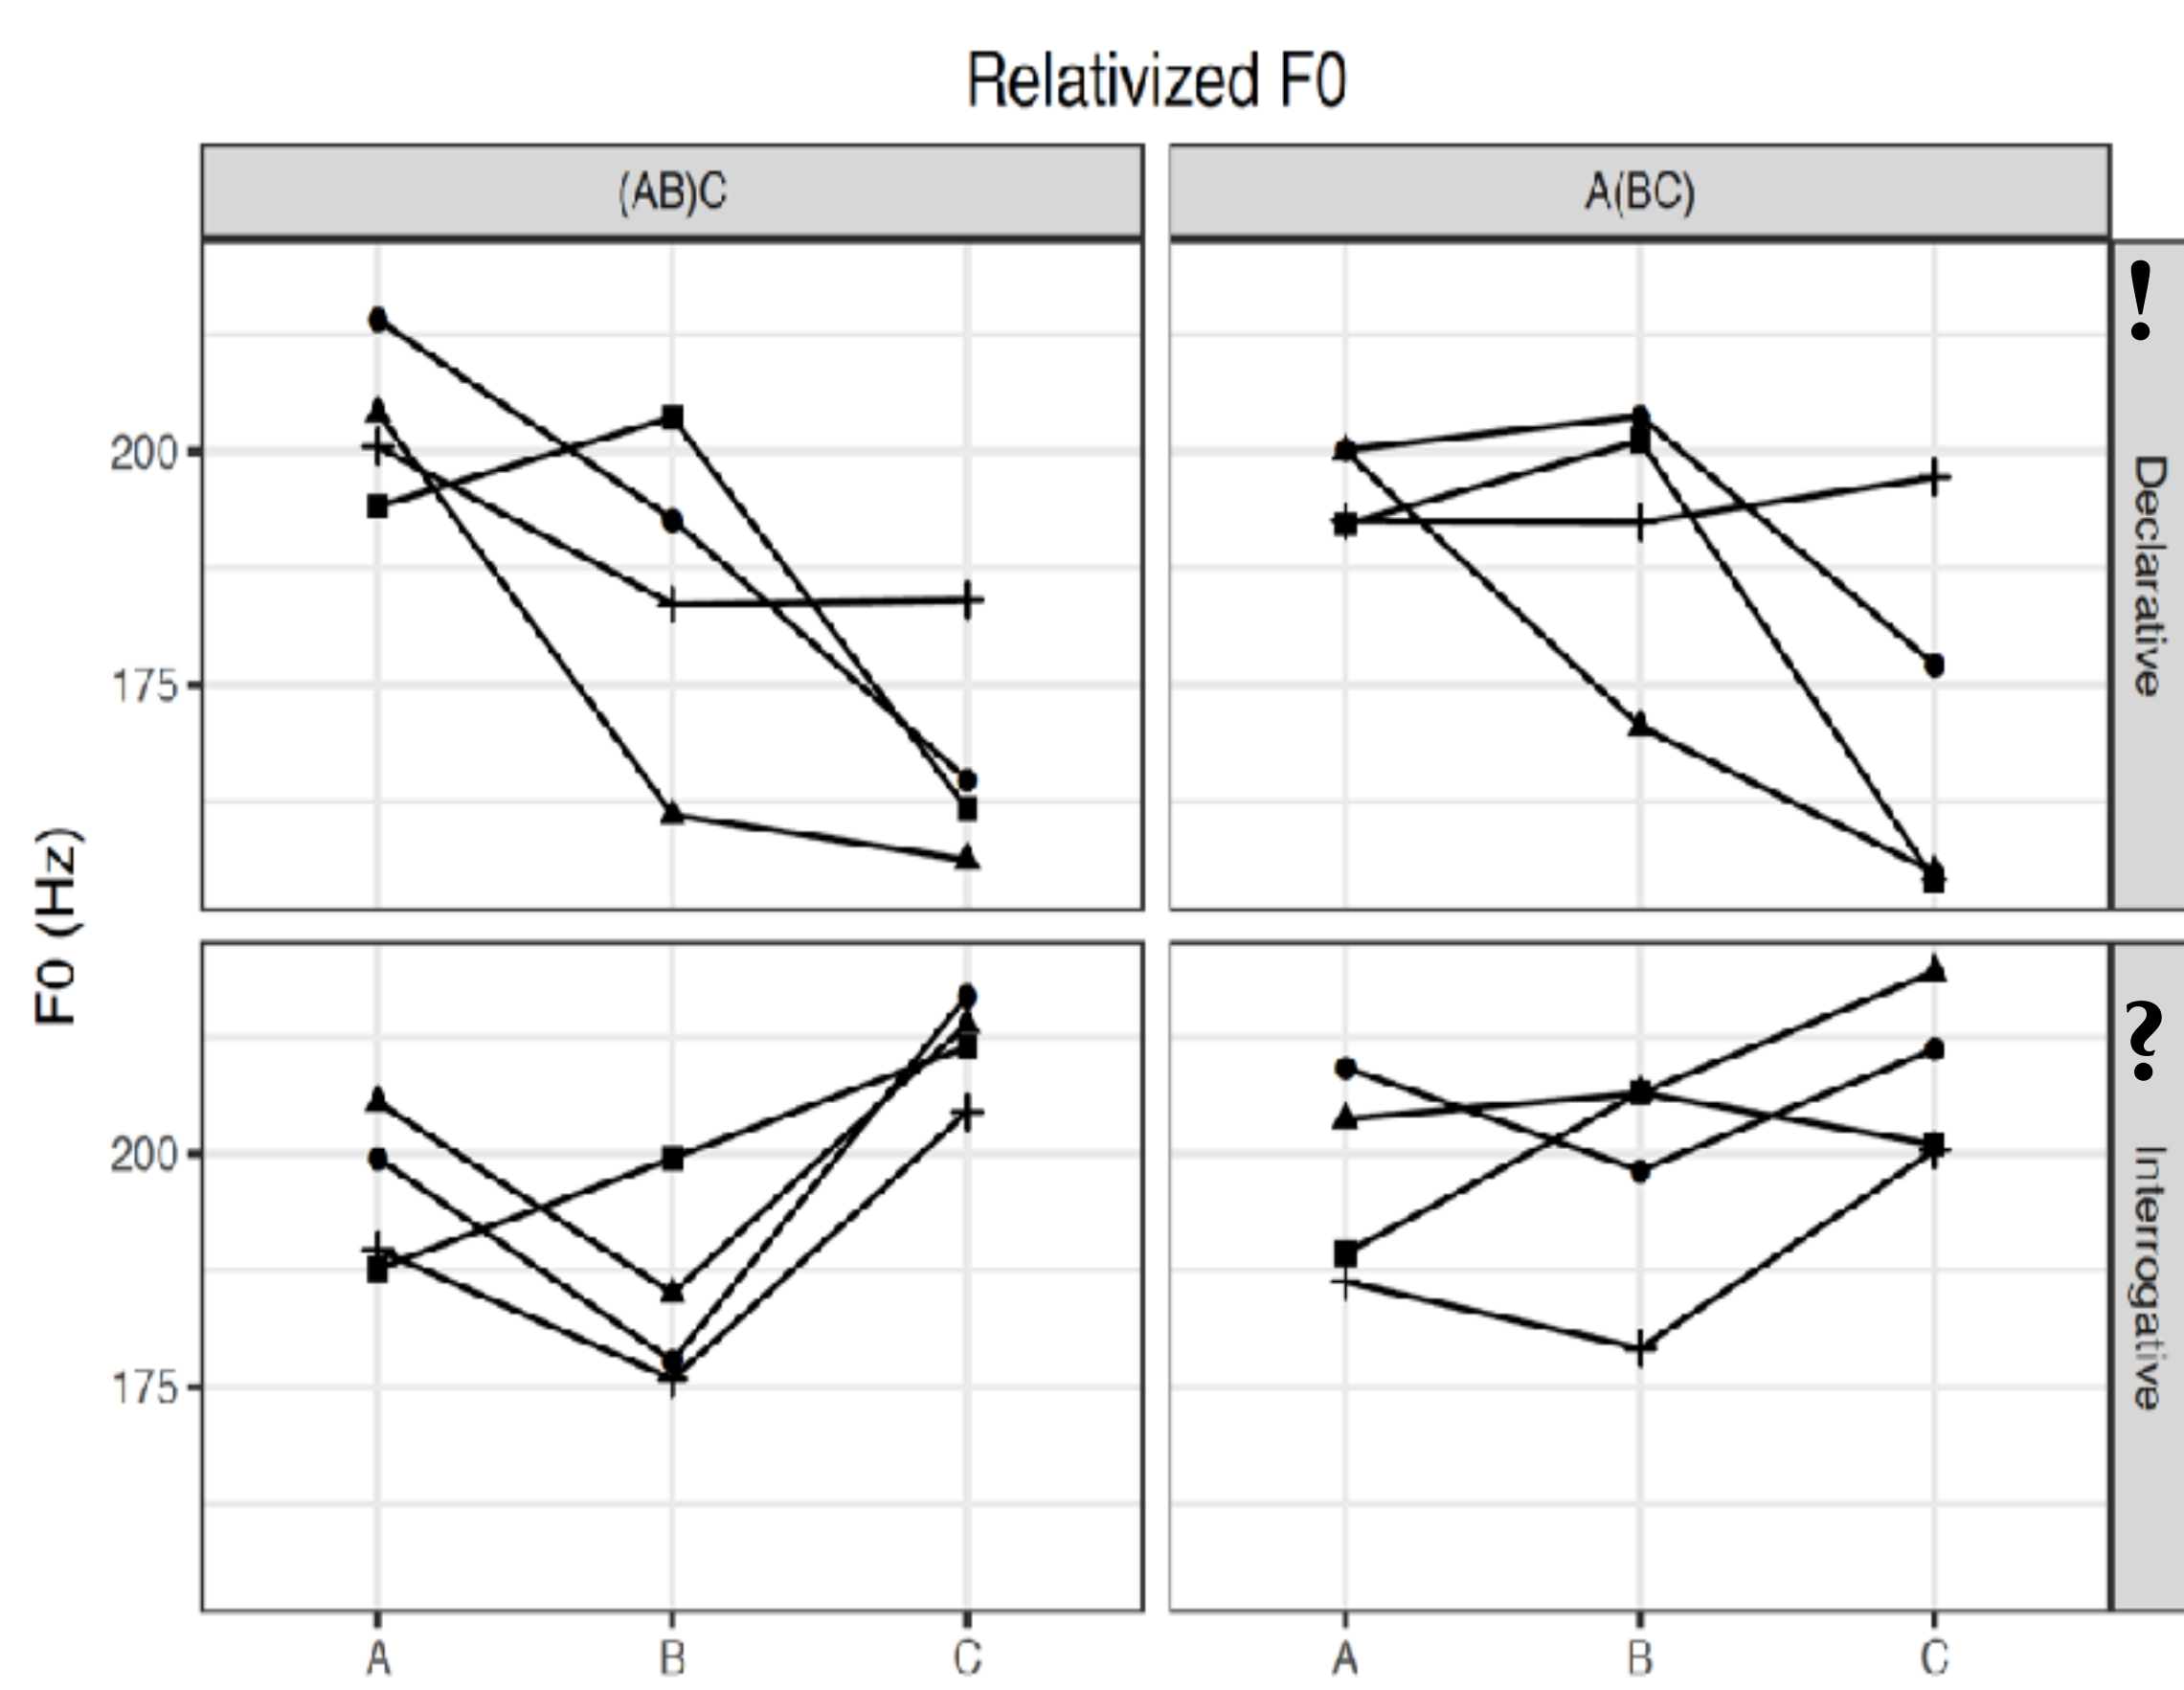

- ! But in fact they said that **Marion or Marvin, and Nolan** arrived.
- ? But you say that **Marion or Marvin, and Nolan** arrived?

A[BC]

ABC I thought they said Sarah, or Marvin and Nolan arrived.  
 ABC I thought they said Marion, or Sarah and Nolan arrived.  
 ABC I thought they said Marion, or Marvin and Sarah arrived.  
 ABC I thought they said Sarah arrived.

- ! But in fact they said that **Marion, or Marvin and Nolan** arrived.
- ? But you say that **Marion, or Marvin and Nolan** arrived?

## Scaling Effect No consistent phrasing pattern across different tunes and foci:

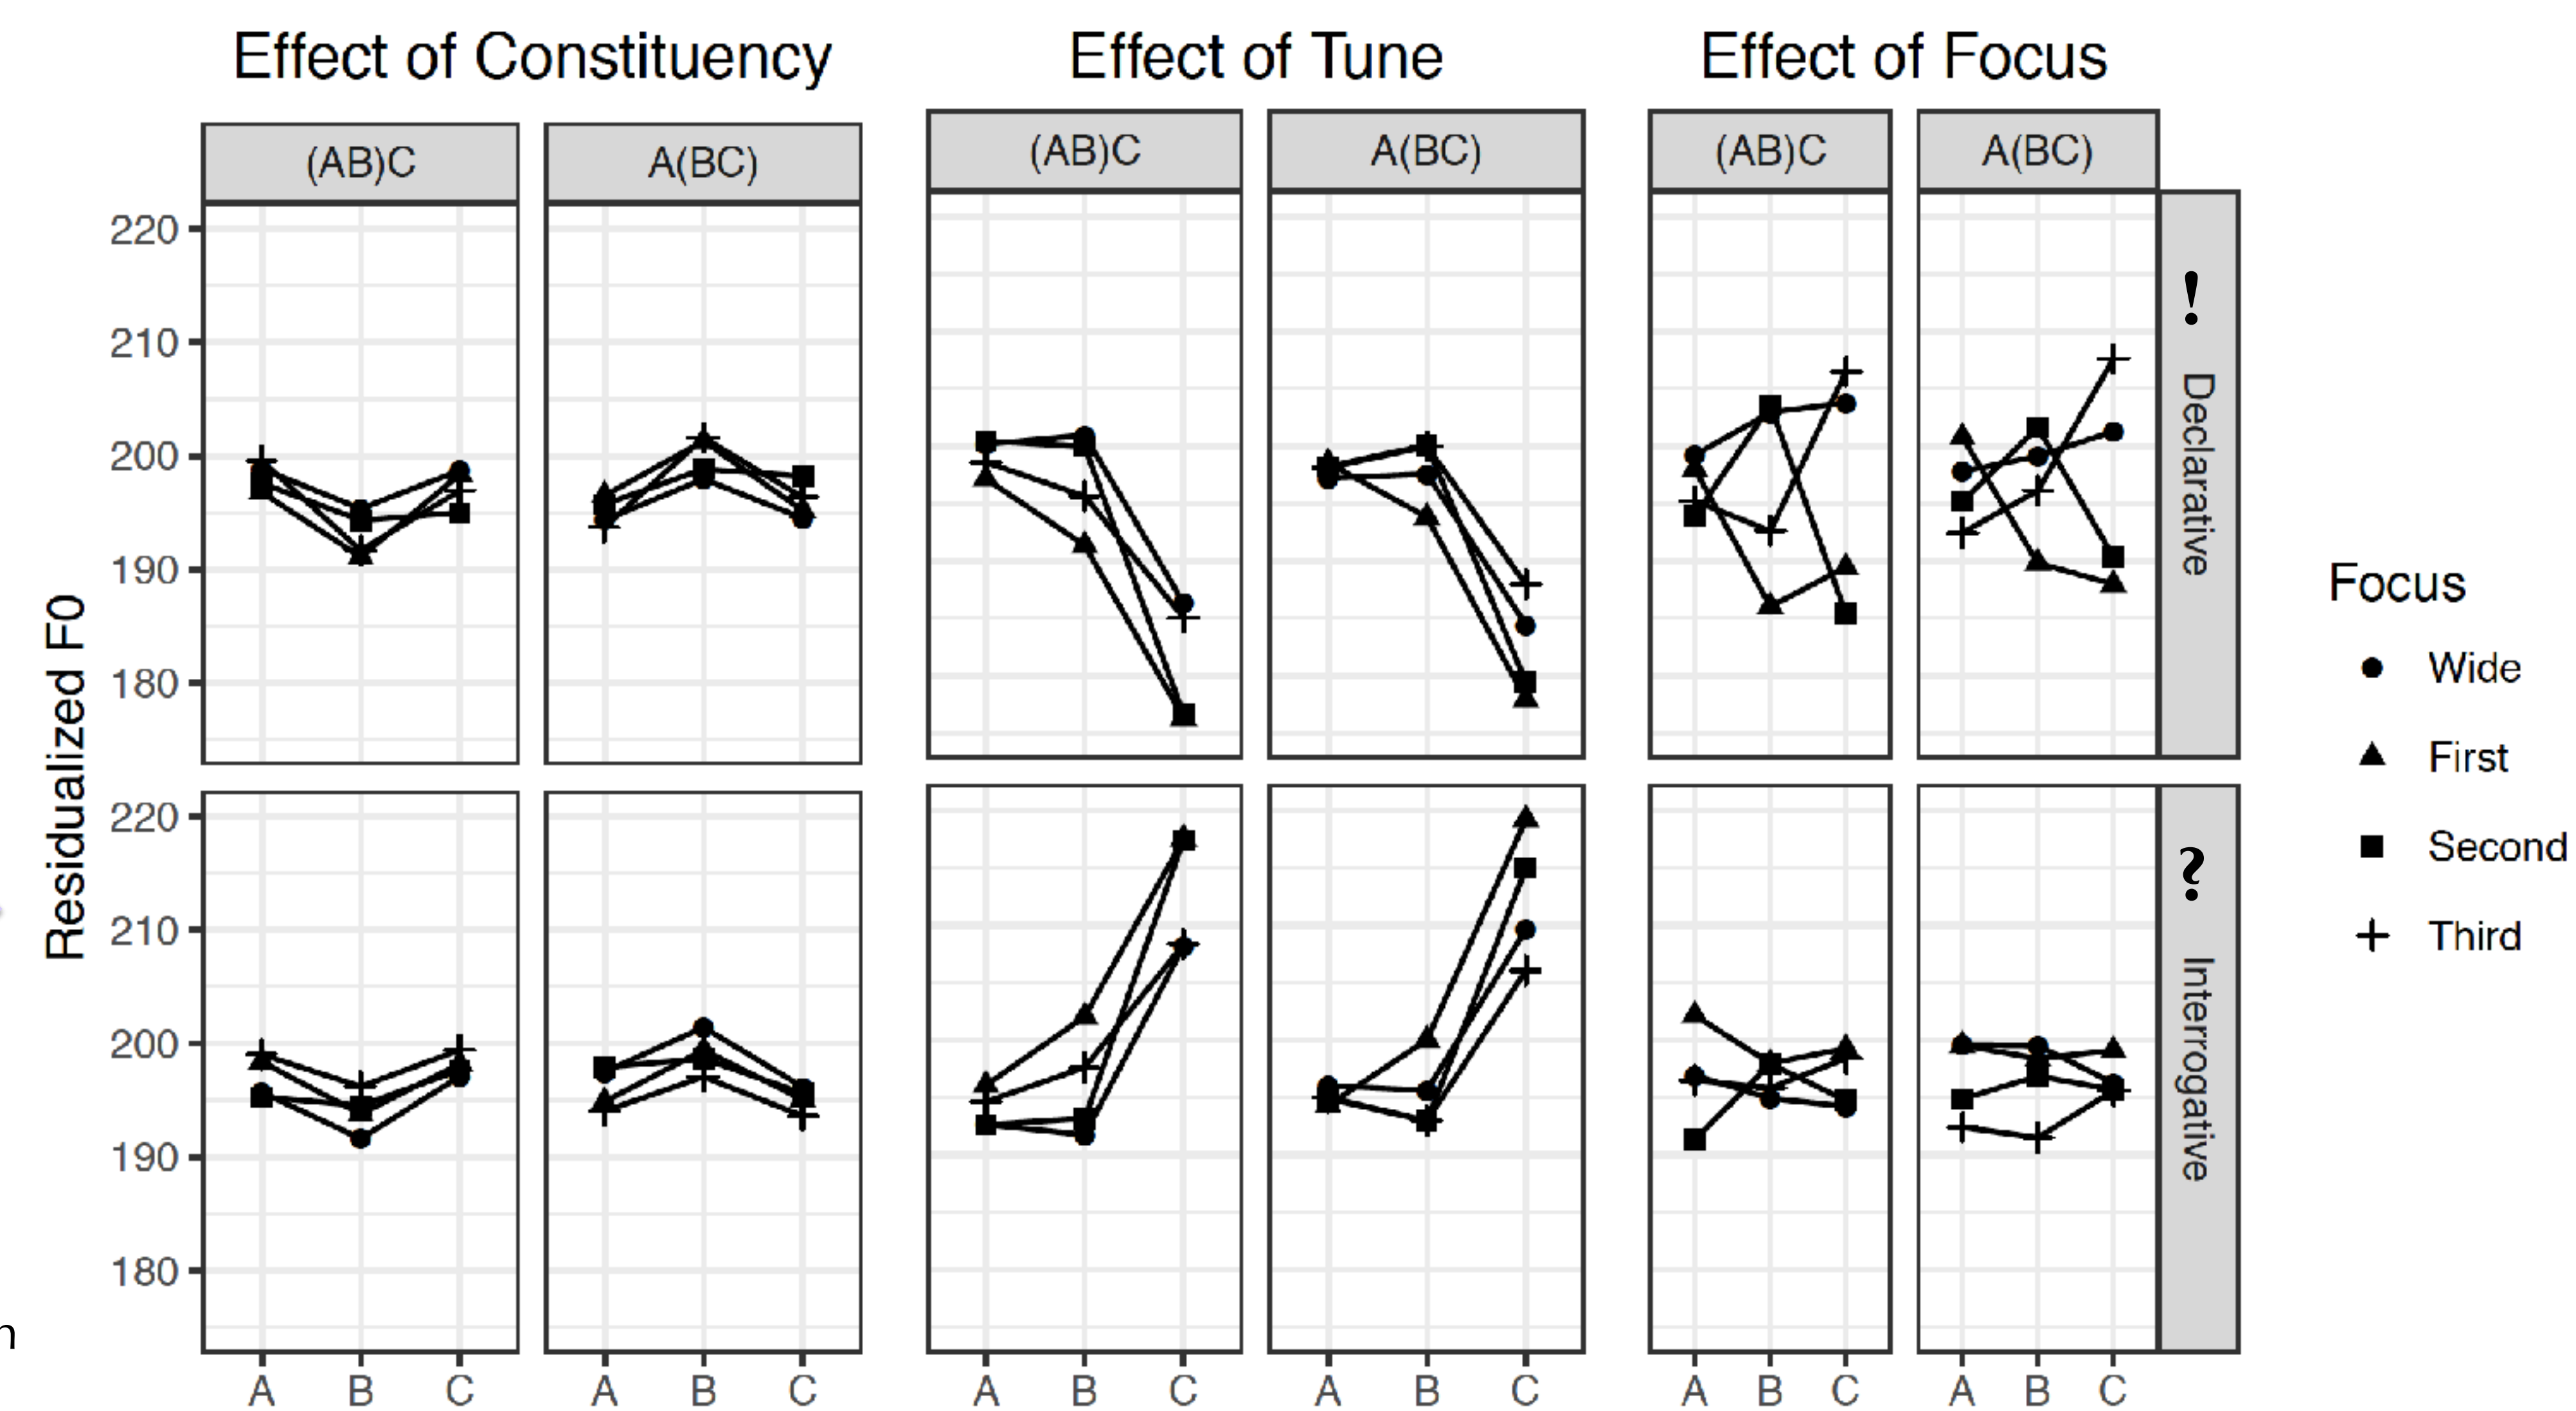

- ★ Aligned with Montreal Forced Aligner (McAuliffe et al. 2017a), normalized with SCT/Polyglot DB (McAuliffe et al. 2017b)
- ★ F0 based on z-scores for expected F0 based on speaker and segmental content, converted back to Hertz for display
- ★ Average measures over entire words
- ★ Disfluent & incorrect utterances were excluded (25%)

Focus  
 ● Wide  
 ▲ First  
 ■ Second  
 + Third

Residualization

- ★ Residualization for each dimension with LMER with other dimensions \* position as fixed effects
- ★ ... and item and participant random effects
- ★ Residualization is used here as a tool to visualize to what extent the contribution of 3 dimensions to pitch is consistent/interactive

## What does this look like? Scaling example with initial focus (focus on first conjunct; question; left vs. right branching):

[AB]C

A[BC]

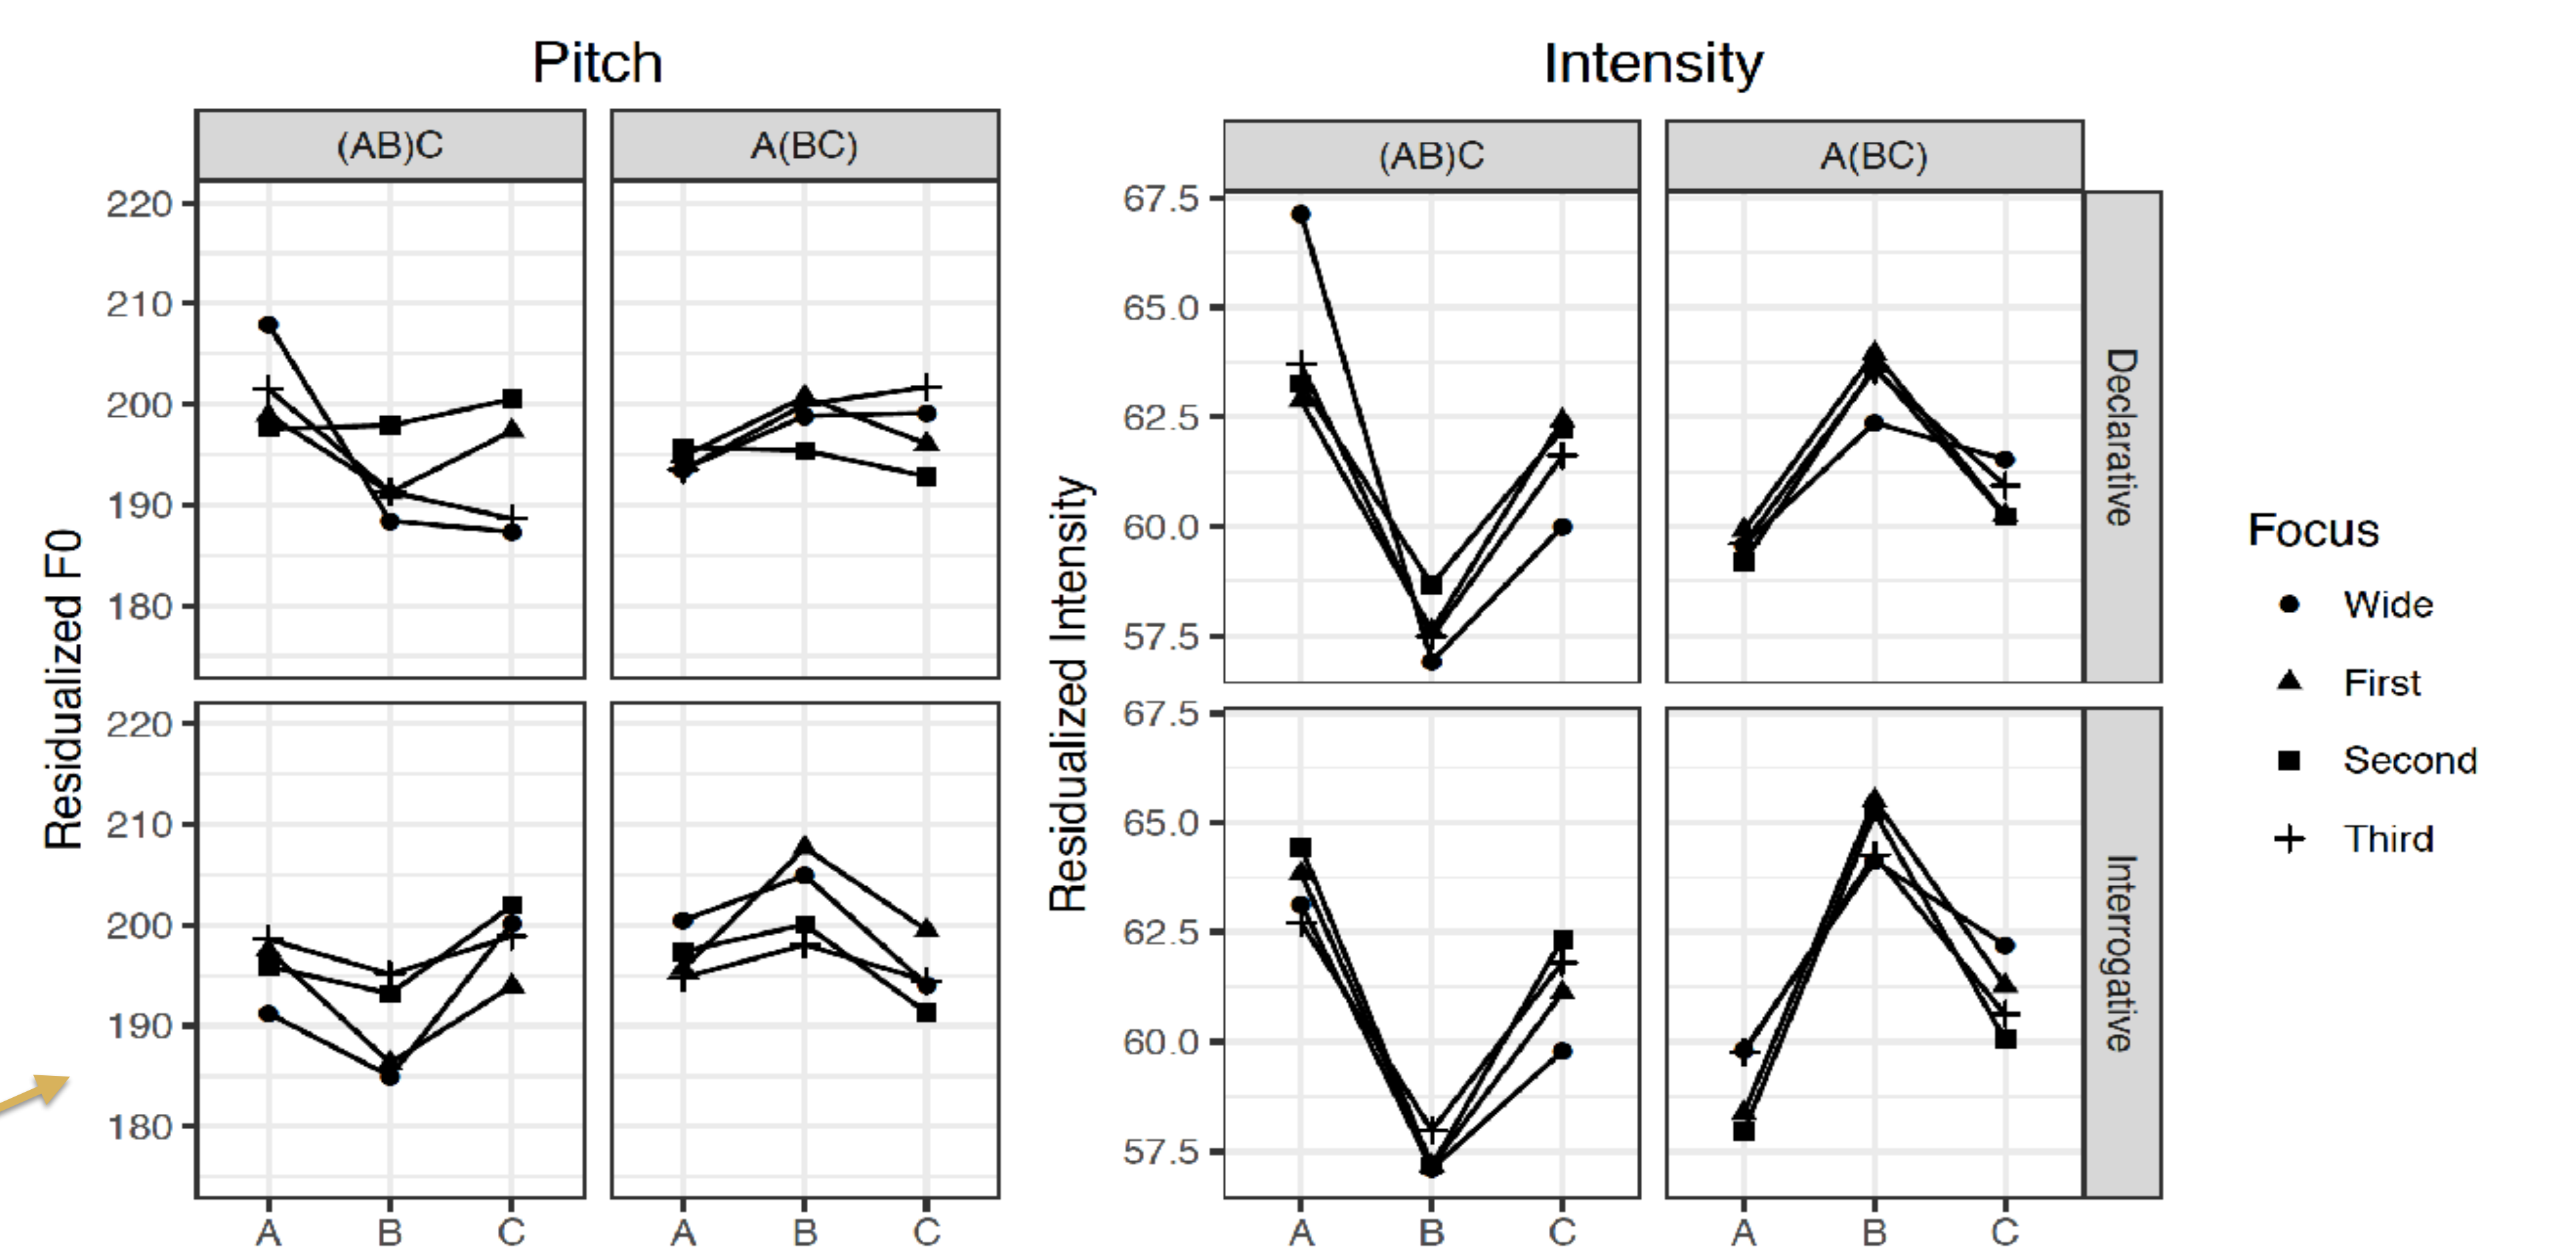

- ★ No apparent obliteration of phrasing effect scaling in postfocal domain
- ★ No apparent difference in phrasing effect between questions and declaratives

- ★ Focus marked differently in questions (interaction between Focus\*Tune)
- ★ Pitch accents lower in questions (L\* vs. H\*)

- ★ Statistical analysis as based not on residuals but complete model; model reveals significant contribution of phrasing with no significant interactions
- ★ Phrasing contributes to pitch in subset of cases where it is expected not do

## But is scaling really about adjusting F0? Pitch correlates highly with intensity; intensity effect is more consistent:

- ★ Gammang et al. 1988: Speakers raise F0 when aiming to talk louder for about a half semi-tone per dB
- ★ Could it be that F0 scaling is a passive reflex of speakers adjusting intensity for rhythmic reasons?

## Did people actually say these according to the manipulation?

- ★ Participants varied in how natural (vs. read) their speech sounded (all utterances are included)
- ★ For each dimension, 2 RAs annotated which tune/focus/phrasing they heard (or annotated 'unclear').
- ★ Inter-annotator agreement was 'almost perfect' for falling vs. rising (Cohen's kappa: 0.96),
- ★ ... 'substantial' for constituency (Cohen's kappa: 0.73) and for prominence (Cohen's kappa: 0.63).
- ★ Based on one annotator:
  - tune (rising vs. falling) 96.3% of the time as expected
  - bracketing 61% (with about one third of sound files marked as 'unclear')
  - prominence 38% (high rate of confusion between wide vs. focus on C; 21% 'unclear').
- ★ We based our pitch vs. intensity plot on the subset of data for which the correct levels for all three dimensions were annotated.
